# Min-wise Hash Family

## Definition (Min-wise Hash Family [Broder, Charikar, Frieze, Mitzenmacher '00])

- We say  $\mathcal{H} = \{h : [N] \rightarrow [M]\}$  is a min-wise hash family with (multiplicative) error  $\delta$ , if for any  $X \subseteq [N]$  and  $y \in X$ ,

$$\Pr_{h \sim \mathcal{H}} [h(y) < \min h(X \setminus y)] := \Pr_{h \sim \mathcal{H}} \left[ h(y) < \min_{x \in X \setminus y} h(x) \right] = \frac{1 \pm \delta}{|X|}.$$

## Definition ( $k$ -min-wise Hash Family [Feigenblat, Porat, Shiftan '11])

- We say  $\mathcal{H} = \{h : [N] \rightarrow [M]\}$  is a  $k$ -min-wise hash family with (multiplicative) error  $\delta$ , if for any  $X \subseteq [N]$  and  $Y \in \binom{X}{\leq k}$ ,

$$\Pr_{h \sim \mathcal{H}} [\max h(Y) < \min h(X \setminus Y)] := \Pr_{h \sim \mathcal{H}} \left[ \max_{y \in Y} h(y) < \min_{x \in X \setminus Y} h(x) \right] = \frac{1 \pm \delta}{\binom{|X|}{|Y|}}.$$

- Play crucial roles in the design of graph algorithms and streaming algorithms

# Problem

- **Goal:** Construct an **explicit** ( $k$ -)min-wise hash family with **small size and error**.
- **Short seed length**  $= \log_2 |\mathcal{H}|$  (number of random bits used to generate a hash function).
- **Explicitness:** This family  $\mathcal{H}$  should be **efficiently computable in polynomial time**.

# Outline

**1<sup>st</sup> STEP – BALLS INTO BINS**

**2<sup>nd</sup> STEP – RECYCLE RANDOMNESS**

**3<sup>rd</sup> STEP – DOMAIN REDUCTION**

$$\Pr_{h \sim \mathcal{H}} [h(y) < \min h(X \setminus y)] = \frac{1 \pm \delta}{|X|}$$
$$= \sum_{\theta=1}^M \Pr_{h \sim \mathcal{H}} [h(y) = \theta \wedge \min h(X \setminus y) > \theta]$$

# Two Level Hash Structure

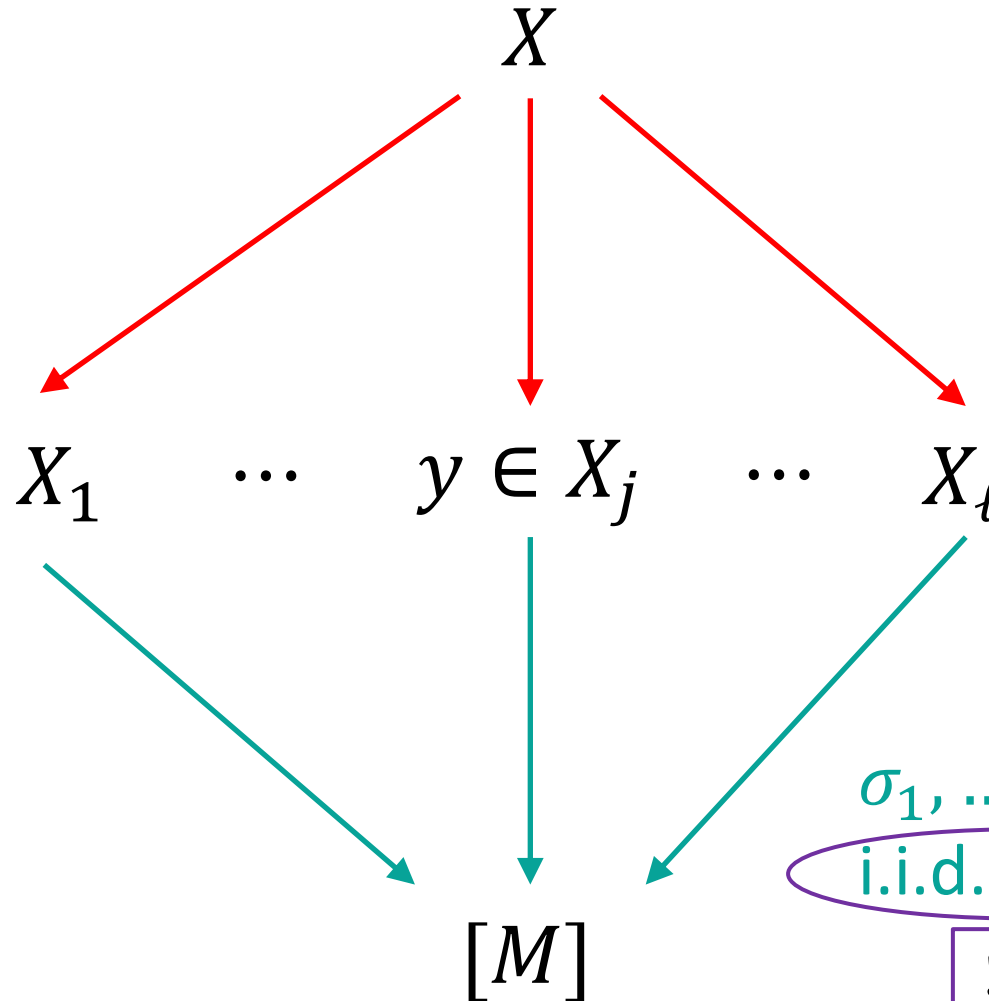

$$h(x) = \sigma_{\varphi(x)}(x)$$

- **Balls into Bins:** small max-load, concentration.

$$|X_i| \approx |X|/\ell, \forall i \in [\ell]$$
$$\max |X_i| \text{ is small}$$

- **Each Block:** Since  $|X_i|$  is small, there exists  $\mathcal{G} = \{\sigma: [N] \rightarrow [M]\}$  with  $|\mathcal{G}| = \text{poly}(N)$ , s.t.

$$\Pr_{\sigma_i \sim \mathcal{G}} [\min \sigma_i(X_i) > \theta]$$
$$\approx \Pr_{h \sim U} [\min h(X_i) > \theta]$$

$\varphi: [N] \rightarrow [\ell]$   
Constant-wise  
independence

$\sigma_1, \dots, \sigma_\ell: [N] \rightarrow [M]$   
i.i.d. from  $\mathcal{G}$

! Require many  
random bits.

# Recycle Randomness

$$\underbrace{(\min \sigma_1(X_1) > \theta)}_{\text{Event } A_1} \wedge \cdots \wedge \underbrace{(\sigma_j(y) = \theta \wedge \min \sigma_j(X_j \setminus y) > \theta)}_{\text{Event } A_j} \wedge \cdots \wedge \underbrace{(\min \sigma_\ell(X_\ell) > \theta)}_{\text{Event } A_\ell}$$

$\sigma_1, \dots, \sigma_\ell$  i.i.d. from  $\mathcal{G}$

$\Leftrightarrow$

$$(\min \sigma'_1(X_1) > \theta) \wedge \cdots \wedge (\sigma'_j(y) = \theta \wedge \min \sigma'_j(X_j \setminus y) > \theta) \wedge \cdots \wedge (\min \sigma'_\ell(X_\ell) > \theta)$$

$\sigma'_1, \dots, \sigma'_\ell$  are correlated

# Nisan-Zuckerman Pseudorandom Generator

## Definition (Extractor)

- $\text{Ext} : \{0, 1\}^p \times \{0, 1\}^d \rightarrow \{0, 1\}^q$  is a  $(k, \varepsilon)$ -extractor, if for any random source  $X$  over  $\{0, 1\}^p$  with min-entropy  $H_\infty(X) \geq k$ , it holds that  $\text{Ext}(X, U_d)$  is  $\varepsilon$ -close to  $U_q$ .

- Nisan-Zuckerman PRG:

$$\text{NZPRG}(w, s_1, \dots, s_\ell) = (\text{Ext}(w, s_1), \dots, \text{Ext}(w, s_\ell)) \in (\{0, 1\}^q)^\ell,$$

$w \sim U_p, s_1, \dots, s_\ell$  i.i.d. from  $U_d$ .

$$\underbrace{(\min \sigma'_1(X_1) > \theta)}_{\text{Event } A_1} \wedge \dots \wedge \underbrace{(\sigma'_j(y) = \theta \wedge \min \sigma'_j(X_j \setminus y) > \theta)}_{\text{Event } A_j} \wedge \dots \wedge \underbrace{(\min \sigma'_\ell(X_\ell) > \theta)}_{\text{Event } A_\ell}$$

$$\begin{aligned} \text{Ext}: \{0, 1\}^p \times \{0, 1\}^d &\rightarrow \mathcal{G} \\ \sigma'_1 &= \text{Ext}(w, s_1), \dots, \sigma'_\ell = \text{Ext}(w, s_\ell) \\ w \sim U_p, s_1, \dots, s_\ell &\text{ i.i.d. from } U_d \end{aligned}$$

# One bin is Sensitive to Multiplicative Error

$$h(x) = \sigma'_{\varphi(x)}(x)$$

$$\Pr_{h \sim \mathcal{H}} [h(y) = \theta \wedge \min h(X \setminus y) > \theta]$$

||

$$\varphi: [N] \rightarrow [\ell]$$

$$\begin{aligned} P_i[\mathcal{G}] &\approx P_i[U] \\ P_i[\text{NZ}] &= \Pr_{\sigma'_i: \text{NZPRG}} [A_i] \\ P_i[\mathcal{G}] &:= \Pr_{\sigma_i \sim \mathcal{G}} [A_i] \\ P_i[U] &:= \Pr_{h \sim U} [A_i] \end{aligned}$$

$$P_1[\text{NZ}] \cdots P_j[\text{NZ}] \cdots P_\ell[\text{NZ}]$$

≈

$$\sigma'_1, \dots, \sigma'_\ell: [N] \rightarrow [M] \text{ from NZPRG, ExtErr} = N^{-o(1)}$$

? We hope that this special bin does not need to pay for the error from extractor.

$$(P_1[U] \pm \text{ExtErr}) \cdots (P_j[U] \pm \text{ExtErr}) \cdots (P_\ell[U] \pm \text{ExtErr})$$

$$P_j[U] = \Pr_{h \sim U} [h(y) = \theta \wedge \min h(X_j \setminus y) > \theta] \leq 1/M \Rightarrow P_j[U] \pm \text{ExtErr} = P_j[U] \cdot (1 \pm M \cdot \text{ExtErr})$$

!  $P_j[U]$  is very small, and it makes this bin very sensitive to multiplicative error.

# Change the Order of Inputs

$$\underbrace{(\min \sigma'_1(X_1) > \theta)}_{\text{Event } A_1} \wedge \cdots \wedge \underbrace{(\sigma'_j(y) = \theta \wedge \min \sigma'_j(X_j \setminus y) > \theta)}_{\text{Event } A_j} \wedge \cdots \wedge \underbrace{(\min \sigma'_\ell(X_\ell) > \theta)}_{\text{Event } A_\ell}$$

$$\begin{aligned} & \text{Ext: } \{0,1\}^p \times \{0,1\}^d \rightarrow \mathcal{G} \\ & \sigma'_1 = \text{Ext}(w, s_1), \dots, \sigma'_\ell = \text{Ext}(w, s_\ell) \\ & w \sim U_p, s_1, \dots, s_\ell \text{ i.i.d. from } U_d \end{aligned}$$

★  $s_1, \dots, s_\ell$  (or correspondingly  $\sigma'_1, \dots, \sigma'_\ell$ ) are symmetric.

# Change the Order of Inputs

$$\underbrace{(\sigma'_j(y) = \theta \wedge \min \sigma'_j(X_j \setminus y) > \theta)}_{\text{Event } A_j} \wedge \underbrace{(\min \sigma'_1(X_1) > \theta)}_{\text{Event } A_1} \wedge \cdots \wedge \underbrace{(\min \sigma'_\ell(X_\ell) > \theta)}_{\text{Event } A_\ell}$$

$$\begin{aligned} \text{Ext}: \{0,1\}^p \times \{0,1\}^d &\rightarrow \mathcal{G} \\ \sigma'_j &= \text{Ext}(w, s_j), \sigma'_1 = \text{Ext}(w, s_1), \dots, \sigma'_\ell = \text{Ext}(w, s_\ell) \\ w &\sim U_p, s_j, s_1, \dots, s_\ell \text{ i.i.d. from } U_d \end{aligned}$$

$$P_j[\text{NZ}] \cdot P_1[\text{NZ}] \cdots P_\ell[\text{NZ}]$$

$\approx$

$$(P_j[U] \pm \text{ExtErr}) \cdot (P_1[U] \pm \text{ExtErr}) \cdots (P_\ell[U] \pm \text{ExtErr})$$

$$H_\infty(w = U_p) = p \geq k$$

$$\Rightarrow \text{Ext}(w, s_j) \approx_{\text{ExtErr}} \mathcal{G}$$

★  $w$  has no entropy loss at the beginning.  
 ? We expect strong properties for  $\sigma'_j = \text{Ext}(w, s_j)$  than other  $\sigma'_i = \text{Ext}(w, s_i)$ .

# Special Extractor

$$P_j[\text{NZ}] \cdot P_1[\text{NZ}] \cdots P_\ell[\text{NZ}]$$

$\approx$

$$(\cancel{P_j[U] \pm \text{ExtErr}}) \cdot (P_1[U] \pm \text{ExtErr}) \cdots (P_\ell[U] \pm \text{ExtErr})$$

$$\begin{aligned} H_\infty(w = U_p) &= p \geq k \\ \Rightarrow \text{Ext}(w, s_j) &\approx_{\text{ExtErr}} \mathcal{G} \\ \sigma'_j = \text{Ext}(w, s_j) &\sim \mathcal{G} \end{aligned}$$

★  $w$  has no entropy loss at the beginning.  
 ? We expect strong properties for  $\sigma'_j = \text{Ext}(w, s_j)$  than other  $\sigma'_i = \text{Ext}(w, s_i)$ .

## Lemma

- Given any  $p$  and  $k < p$ , for any error  $\varepsilon$ , there exists an explicit  $(k, \varepsilon)$ -extractor  $\text{Ext}: \{0,1\}^p \times \{0,1\}^d \rightarrow \{0,1\}^q$  with  $q = k/2$  and  $d = O(\log(p/\varepsilon))$ . And  $\text{Ext}$  satisfies an extra property:  $\text{Ext}(U_p, s) = U_q$  for any fixed seed  $s$ .

# Open Problems

Smaller error with optimal seed length?

Extending the result for larger  $k$  (like  $\sqrt{N}$ ) on  $k$ -min-wise hash?

Faster evaluation time with optimal seed length?

Thank you for listening!
